Que-3 :- Explain Password Cracking Tools:
pwdump7, Medusa and Hydra

Ans :

1. pwdump7

What It Is

pwdump7 is a Windows password hash extraction tool.

It attempts to obtain password hashes from the Windows:

- SAM database (Security Account Manager)
- SYSTEM registry hive

The tool itself does not directly crack passwords. It extracts password hashes that can later be audited with authorized password-analysis tools.

2. Medusa

What It Is

Medusa is a parallelized login testing tool.

It is designed for:

- Credential auditing
- Authentication testing
- Service login validation

It supports multiple protocols.

3. THC Hydra

What It Is

Hydra (often called THC Hydra) is one of the most widely known network login auditing tools.

It is designed to test:

- Username/password combinations
- Authentication resilience
- Service exposure

Que-4 :- Explain Types of Steganography with QuickStego and Echo

Ans : Image Steganography :-

Image steganography is a technique used to hide secret information inside digital image files without creating

visible changes to the image. The hidden data is usually stored by modifying tiny pixel values that the human eye cannot easily detect.

- Audio Steganography :-

Audio steganography is the process of concealing secret data inside audio files such as WAV or MP3 by making slight modifications to sound signals that are difficult for human ears to notice. One important method in audio steganography is called echo hiding.

- Video Steganography :-

Video steganography is an advanced form of steganography where secret information is hidden inside video files by combining image and audio steganography techniques together. Since videos contain thousands of image frames along with audio tracks..

Web Scripting Virus

Que-6 :- Explain any one Antivirus with example.

Ans : Microsoft Defender Antivirus is a built-in security solution developed by Microsoft to protect computers from viruses, malware, ransomware, spyware, and other cyber threats. It comes pre-installed with modern versions of the Windows 11 and Windows 10 operating systems, making it one of the most widely used antivirus solutions in the world. Defender continuously scans files, applications, downloads, and system activities in real time to detect suspicious behavior and block harmful software before it can damage the system. It also receives frequent cloud-based threat intelligence updates, allowing it to recognize newly discovered malware quickly.

For example, if a user downloads an infected file from the internet, Microsoft Defender can automatically scan

the file, detect malicious code signatures or suspicious behavior, quarantine the file, and warn the user before the malware executes. It also includes features such as firewall integration, ransomware protection, phishing detection, and controlled folder access to protect sensitive files from unauthorized modification. In modern cybersecurity, antivirus software like Microsoft Defender acts like a silent digital guardian — always watching system activity in the background, standing between ordinary users and the endless storm of threats moving across the internet every second.
